Typically, spatio-temporal data is given at a set of discrete locations  $s_i \in S$  and time steps  $t_j \in T$ .

We desire a full spatio-temporal random field  $Z$  modelling the process at any location  $(s, t)$  in space and time.

Here, we look at daily fine dust concentrations across Europe ( $PM_{10}$ ).

## Problem

### Solution

- Vine-Copulas
- Bivariate Spatial Copula
- Spatio-Temporal Vine-Copula interpolation
- Software

### Application to $PM_{10}$

- Fitment
- Goodness of fit

### Conclusion & Outlook

### References

We assume a stationary and isotropic process across the region  $S$  and the time frame  $T$ .

This allows us to consider lag classes by distances in space and time instead of single locations in space.

Copulas describe the dependence structure between the margins of a multivariate distribution. Sklar's Theorem states:

$$H(x_1, \dots, x_d) = C(F_1(x_1), \dots, F_d(x_d))$$

where  $H$  is any multivariate CDF,  $F_1, \dots, F_d$  are the corresponding marginal univariate CDFs and  $C$  is a suitable *copula* (uniquely determined in a continuous setting).

Since  $F_i(X_i) \sim U(0, 1)$ , copulas can be thought of as CDFs on the unit (hyper-)cube.

## Vine-Copula

Bivariate copulas are pretty well understood and rather easy to estimate.

Unfortunately, most bivariate families do not nicely extend to a multivariate setting or lack the necessary flexibility.

*Vine-Copulas* allow to approximate multivariate copulas by mixing (conditional) bivariate copulas following a vine decomposition.

**Figure:** A 4-dim canonical vine decomposition.

We decompose the ten dimensional distribution into its marginal distribution  $F$  (identical for all 10 margins) and a vine copula:

On the first tree, we use a spatio-temporal bivariate copula accounting for spatial and temporal distance.

The following trees are modelled from a wide set of "classical" bivariate copulas.

## Density of the spatial and spatio-temporal copula

The density of the *bivariate spatial copula* is then given by a convex combination of bivariate copula densities:

$$c_h^\Delta(u, v) := \begin{cases} c_1^\Delta(u, v) & , 0 \leq h < l_1 \\ (1 - \lambda_2)c_1^\Delta(u, v) + \lambda_2c_2^\Delta(u, v) & , l_1 \leq h < l_2 \\ \vdots & \vdots \\ (1 - \lambda_k)c_{k-1}^\Delta(u, v) + \lambda_k \cdot 1 & , l_{k-1} \leq h < l_k \\ 1 & , l_k \leq h \end{cases}$$

where  $\lambda_j := \frac{h-l_{j-1}}{l_j-l_{j-1}}$ .

The density of the *bivariate spatio-temporal copula*  $c_{h,\Delta}(u, v)$  is then given by a convex combination of bivariate spatial copula densities in an analogous manner.

## The full density

The remaining copulas  $c_{j,j+i|0,\dots,j-1}$  with integers  $1 \leq j \leq 9, 1 \leq i \leq 9 - j$  are estimated over the nine dimensional conditional sample

$$(F_{\mathbf{h},\Delta}(\mathbf{X}_{s_1,t_0} | \mathbf{X}_{s_0,t_0}), \dots, F_{\mathbf{h},\Delta}(\mathbf{X}_{s_3,t_{-2}} | \mathbf{X}_{s_0,t_0})).$$

We get the full 10-dim copula density as a product of all involved bivariate densities:

$$\begin{aligned} & c_{\mathbf{h},\Delta}(u_0, \dots, u_9) \\ &= \prod_{i=1}^9 c_{h,\Delta}(u_0, u_i) \cdot \prod_{j=1}^{9-1} \prod_{i=1}^{9-j} c_{j,j+i|0,\dots,j-1}(u_j|_{0,\dots,j-1}, u_{j+i}|_{0,\dots,j-1}) \end{aligned}$$

Where  $u_0 = F(Z(s_0, t_0)), \dots, u_9 = F(Z(s_3, t_{-2}))$ ,

$$u_j|_0 = F_{h,\Delta}(u_j|u_0) = \frac{\partial C_{h,\Delta}(u_0, u_j)}{\partial u_0} \text{ and}$$

$$\begin{aligned} u_{j+i}|_{0,\dots,j-1} &= F_{j+i|0,\dots,j-1}(u_{j+i}|u_0, \dots, u_{j-1}) \\ &= \frac{\partial C_{j-1,j+i|0,\dots,j-2}(u_{j-1}|_{0,\dots,j-2}, u_{j+i}|_{0,\dots,j-2})}{\partial u_{j-1}|_{0,\dots,j-2}} \end{aligned}$$

The estimate can be obtained as the expected value

$$\hat{Z}_m(s_0, t_0) = \int_{[0,1]} F^{-1}(u) c_{h,\Delta}(u|u_1, \dots, u_9) du$$

or by calculating any percentile  $p$  (i.e. the median)

$$\hat{Z}_p(s_0) = F^{-1}(C_{h,\Delta}^{-1}(p|u_1, \dots, u_9))$$

with the conditional density

$$c_{h,\Delta}(u|u_1, \dots, u_9) := \frac{c_{h,\Delta}(u, u_1, \dots, u_9)}{\int_0^1 c_{h,\Delta}(v, u_1, \dots, u_9) dv}$$

and  $u_1 = F(Z(s_1, t_0)), \dots, u_9 = F(Z(s_3, t_{-2}))$  as before.
