# Spatial/spatio-temporal data

The `spcopula`  
R-package:  
Modelling Spatial  
and  
Spatio-Temporal  
Dependence with  
Copulas

Benedikt Gräler

Typically, spatial/spatio-temporal data is given at a set of discrete locations  $s_i \in S$  (and time steps  $t_j \in T$ ).

We desire a full spatial/spatio-temporal random field  $Z$  modelling the process at any location  $s$  in space/( $s, t$ ) in space and time.

We will look at daily mean fine dust concentrations across Europe ( $PM_{10}$ ).

In the following, we will refer to  $Z$  as a spatio-temporal random field (including the spatial case).

# Copulas

The `spcopula`  
R-package:  
Modelling Spatial  
and  
Spatio-Temporal  
Dependence with  
Copulas

Benedikt Gräler

Copulas describe the dependence structure between the margins of a multivariate distribution. Sklar's Theorem states:

$$H(x_1, \dots, x_d) = C(F_1(x_1), \dots, F_d(x_d))$$

where  $H$  is any multivariate CDF,  $F_1, \dots, F_d$  are the corresponding marginal univariate CDFs and  $C$  is a suitable *copula* (uniquely determined in a continuous setting).

Since  $F_i(X_i) \sim U(0, 1)$ , copulas can be thought of as CDFs on the unit (hyper-)cube.

## Conclusion & Outlook

## References

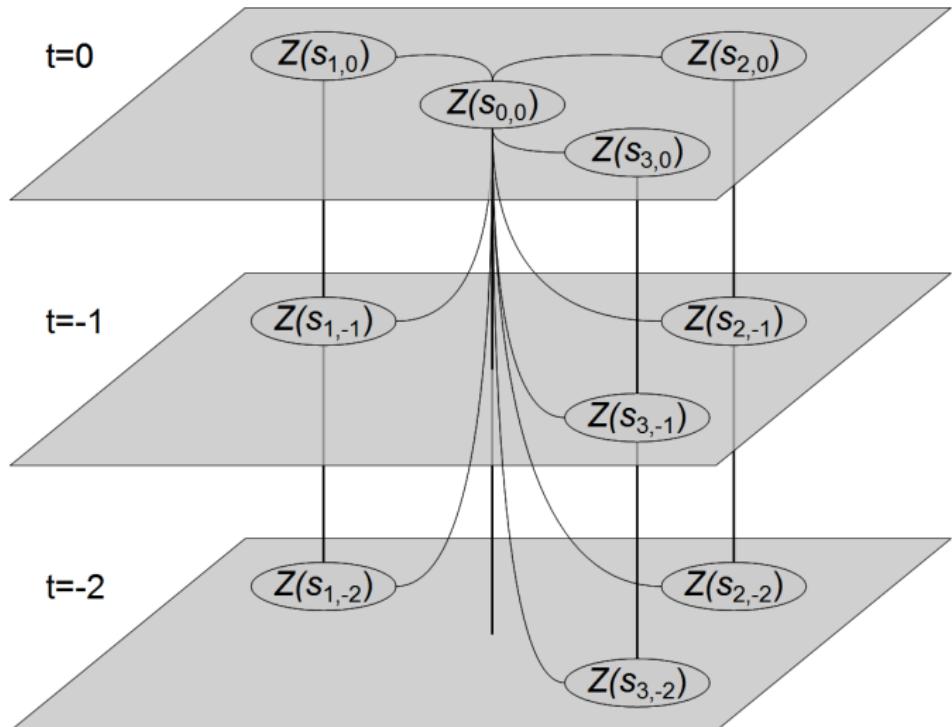

- Bivariate copulas are pretty well understood and rather easy to estimate.
- Unfortunately, most bivariate families do not nicely extend to a multivariate setting or lack the necessary flexibility.
- *Vine Copulas* allow to approximate multivariate copulas by mixing (conditional) bivariate copulas following a vine decomposition [ACFB09, BC02].

# Spatio-temporal vine copulas

The `spcopula`  
R-package:  
Modelling Spatial  
and  
Spatio-Temporal  
Dependence with  
Copulas

Benedikt Gräler

The distribution of local neighbourhoods is decomposed into marginal distributions  $F_i$  and a *spatio-temporal vine copula*:

- The first tree is modelled as bivariate spatio-temporal copulas accounting for spatial and temporal distances.
- Remaining trees are modelled from a wide set of "classical" bivariate copulas as a vine or truncated vine.

# Accounting for spatial distance

The **spcopula**  
R-package:  
Modelling Spatial  
and  
Spatio-Temporal  
Dependence with  
Copulas

Benedikt Gräler

Thinking of pairs of spatio-temporal locations  
 $((s_1, t_1), (s_2, t_2))$  we assume ...

distance has a strong influence on the strength of dependence

dependence structure is identical for all neighbours, but may change with distance

stationarity and build  $k$  bins by distance to estimate a bivariate copula  $c_{j,h}(u, v)$  for all spatial bins  $[0, l_1], [l_1, l_2], \dots, [l_{k-1}, l_k]$  per temporal lag.

# Density of the spatial and spatio-temporal copula

The `spcopula`  
R-package:  
Modelling Spatial  
and  
Spatio-Temporal  
Dependence with  
Copulas

Benedikt Gräler

The density of the *bivariate spatial copula* is then given by a convex combination of bivariate copula densities:

$$c_h^\Delta(u, v) := \begin{cases} c_{1,h}^\Delta(u, v) & , 0 \leq h < l_1 \\ (1 - \lambda_2)c_{1,h}^\Delta(u, v) + \lambda_2 c_{2,h}^\Delta(u, v) & , l_1 \leq h < l_2 \\ \vdots & \vdots \\ (1 - \lambda_k)c_{k-1,h}^\Delta(u, v) + \lambda_k \cdot 1 & , l_{k-1} \leq h < l_k \\ 1 & , l_k \leq h \end{cases}$$

where  $\lambda_j := \frac{h - l_{j-1}}{l_j - l_{j-1}}$ .

The density of the *bivariate spatio-temporal copula*  $c_{h,\Delta}(u, v)$  is then given by a convex combination of bivariate spatial copula densities in an analogous manner.

# The full density

The **scopula**  
R-package:  
Modelling Spatial  
and  
Spatio-Temporal  
Dependence with  
Copulas

Benedikt Gräler

The remaining copulas  $c_{j,j+i|0,\dots,j-1}$  are estimated over the conditional sample.

We get the full (here 10-dim) spatio-temporal vine copula density as a product of all involved bivariate densities:

$$c_{\mathbf{h},\Delta}(u_0, \dots, u_9) = \prod_{i=1}^9 c_{h,\Delta}(u_0, u_i) \cdot \prod_{j=1}^{9-1} \prod_{i=1}^{9-j} c_{j,j+i|0,\dots,j-1}(u_{j|0,\dots,j-1}, u_{j+i|0,\dots,j-1})$$

# Spatio-temporal vine copula interpolation

The **spcopula**  
R-package:  
Modelling Spatial  
and  
Spatio-Temporal  
Dependence with  
Copulas

The estimate can be obtained as the expected value

$$\widehat{Z}_m(s_0, t_0) = \int_{[0,1]} F^{-1}(u) c_{\mathbf{h}, \Delta}(u|u_1, \dots, u_d) du$$

or by calculating any percentile  $p$  (i.e. the median)

$$\widehat{Z}_p(s_0, t_0) = F^{-1}(C_{\mathbf{h}, \Delta}^{-1}(p|u_1, \dots, u_d))$$

with the conditional density

$$c_{\mathbf{h}, \Delta}(u|u_1, \dots, u_d) := \frac{c_{\mathbf{h}, \Delta}(u, u_1, \dots, u_d)}{\int_0^1 c_{\mathbf{h}, \Delta}(v, u_1, \dots, u_d) dv}$$

and  $u_i = F_i(Z(s_i, t_i))$ .
